Now, You can Hack Subway Surfers. You can get unlimited coins and keys. It can be use on 2 computers 2 PS4 and IOS. Q: How to handle API requests properly? I'm building a very simple web app using Flask and Google App Engine Standard. The data model is a simple table called "Emails", which contains a list of email addresses. The workflow for creating an email works like this: The user enters an email address and presses "Send". The flask app posts the request to a Google Cloud Endpoints API gateway. Cloud Endpoints queries the backend GQL database for the relevant entity. Cloud Endpoints returns the entity to the flask app. The flask app sends the email to the user. Everything works fine for my basic needs, but I have to get really "Googley" to make sure I'm compliant with their API rules. For example, some email clients don't (or shouldn't) work with email addresses that aren't valid. This is a massive pain for my users. How can I make my API request conditional, for instance, checking if the address exists in the database before sending out a successful response? I suppose I could parse the request and query the database before sending a response, but this is a pretty poor performance solution (particularly when I'm sending a response based on the size of the request). Do some email clients (like Gmail) let the user send an email to an invalid address? Can I use a feature like that to send an error to my users? I'm pretty new to API design, so I'm looking to get some advice on the following points: What kind of design considerations should I make for my API requests? Should I be asking users to verify their email address before being able to send an email to it? Is the out-of-band approach I f678ea9f9e
